# Export Survival and Comparative Advantage

**(Work in progress)**

---

Regional Seminar on Export Diversification, October 27-28, 2010

Bolormaa Tumurchudur, UNCTAD

Miho Shirotori, UNCTAD

Alessandro Nicita, UNCTAD

---

# Overview

- **Export growth can be boosted**
    - By exporting more of existing products (at the intensive margin)
    - By exporting more new products (at the extensive margin)
    - By fewer failures of exports (at the sustainability margin)
  - **Extensive margin growth is more important than intensive margin growth**
    - Hummels & Klenow (2005), Pham & Martin (2007), Brenton & Newfarmer (2007, 2009)
  - **Durations of export relations are very low: median export spell length is one to two years**
    - Besedes & Prusa (2006), Nitsch (2007)
  - **Therefore the key element to achieving higher export growth are longer bilateral trade-relationships and higher survival rates of those.**
    - However product churning is necessary to select core products
  - **It is important for the design of export-promotion policies to search for robust and policy related determinants of export survival.**
-

---

# Research question

- What is the role of comparative advantage in Export Duration?

---

# Outline

- Overview
  - Literature on Export Survival Determinants
  - How to define the product with Comparative Advantage?
  - Export duration: Prima-facie evidence
  - Survival Analysis
  - Results: Stratified Cox PH Model estimation
  - Conclusion
-

---

# Empirical Studies on Export Survival

- Seminal work of Besedes & Prusa (2006a)
  - Nitsch (2009)
    - - using 10 year panel of German Imports he found that gravity variables influenced the duration of trade flows
  - Fugazza & Molina (2009)
    - extended the panel of bilateral flows between 96 countries using, as regressors, gravity variables and time required for export procedures as proxies for fixed costs.
  - Obashi (2009)
    - found that vertical relationships have lower hazard rates than the exports of final goods and that they are less sensitive to trade costs
  - Growing number of papers have used firm-level datasets:
    - Gorg et al. (2008) have found that longer survival for products located close to the firm's core competencies and to the country's comparative advantage by using Hungarian firm level data,
    - Carballo & Volpe (2008) studied how diversification strategies affect survival of firm level activity by using Peruvian firm level data.
-

---

## Role of Comparative advantage in Export Survival: How to define the product with comparative advantage?

- Identify comparative advantage of a product is one way of providing guidance of supporting a particular sector (pick winners)
  - However as the traditional measure Balassa's RCA index defines country's current trade pattern, it cannot be used
  - UNCTAD developed an alternative approach by building a recent database on Revealed Factor Intensity Indices at the Product Level. It extended the PRODY index developed by Hausman, Hwank and Rodrik (2005) to Revealed Factor Intensities.
-

# Revealed Factor Intensity Indices

- Methodology inspired by Hausmann, Hwang & Rodrik (2007)

- RFI for each traded good is calculated as a weighted average of the factor abundance of the countries exporting that good.  $\longrightarrow$   $RFII_k(t) = \sum \omega_k^i e^i$   
 $e^i \Rightarrow \{k^i, h^i, l^i\}$

- Weights are a variant of Balassa's RCA indices  $\longrightarrow$   $\omega_k^i = \frac{X_k^i / X^i}{\sum_i (X_k^i / X^i)}$

# Distance to Comparative Advantage

- Euclidean distance between the vector of the country's endowments and the vector of the product revealed factor intensity
- We standardized the absolute differences between the product factor intensities and the country's factor endowments to have zero mean and unit variance.

$$D_{ck} = \sqrt{\text{std}(k_c - \hat{k}_k)^2 + \text{std}(h_c - \hat{h}_k)^2 + \text{std}(l_c - \hat{l}_k)^2}$$

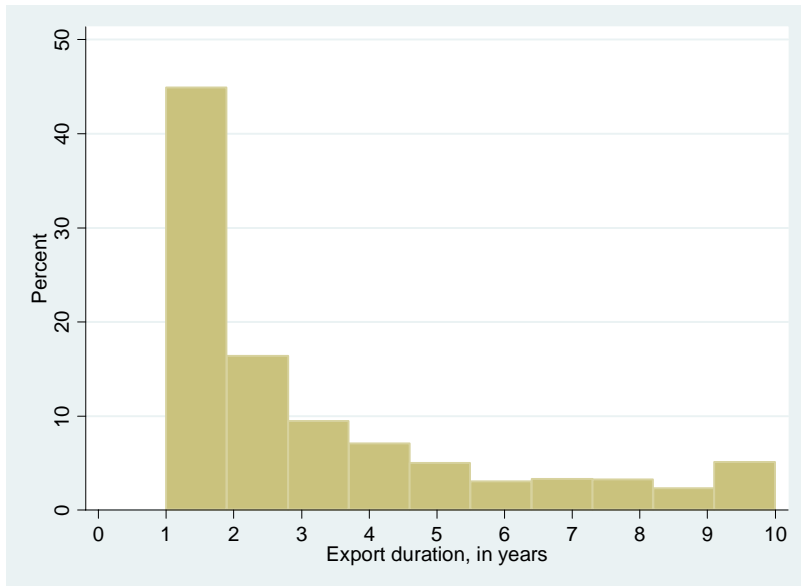

$k_c, h_c, l_c$  -country's human capital, capital and land endowments

$\hat{k}_k, \hat{h}_k, \hat{l}_k$  -revealed factor intensities of product k

# Export duration: Prima-facie evidence

Distribution of Export duration, uncensored observations

|                                | time at risk      | Incidence rate | No. Of subjects  | Median duration |

# Survival Analysis: Introduction

- Allows us to focus on the long-term sustainability of trade relationships
  - Export duration represents the number of years during which country  $c$  exports  $k$  products to its partners
- Allows us to deal with non negative survival times and their skewed distributions
- Allows us to deal with censored observations

---

# Survival Analysis

Examine the relationship between survival times distribution and some covariates of interest.

- Non parametric: Kaplan Meier Survival Estimation
  - Semi-parametric: Cox Proportional Hazard Model
  - Database
    - on bilateral trade flows from 1993-2003
    - 93 exporters (26 North countries, 49 DCs and 18 LDCs)
    - Distance to comparative advantage (UNCTAD data on Revealed Factor Intensity Indices at the HS 6 digit level)
-

# Non-parametric Analysis: Kaplan Meier

$$\hat{S}(t) = \prod_{t_j \leq t} \left( \frac{n_j - d_j}{n_j} \right)$$

The probability that a trade relationship will survive longer than time  $t$ .

# Semi-parametric Cox Proportional Hazard Model

The Cox Proportional Hazard regression model is given by

$$h\langle t | X \rangle = h(t) \exp(X_1 \beta_1 + \dots + X_p \beta_p)$$

- The predictors,  $X_1, \dots, X_p$  are assumed to act additively on  $\log h\langle t | x \rangle$ .
- $\log h\langle t | x \rangle$  changes linearly with the  $\beta$  s.
- The effect of the predictors is the same at all times  $t$ .
- Makes no assumption about the form of  $h(t)$

The Stratified Cox Model allows the form of the underlying hazard function to vary across levels of stratification variables.

$$h\langle t | X, Z = j \rangle = h_j(t) \exp(X\beta), j = 1, \dots, C \text{ (number of levels in } Z)$$

# Estimation results: Comparative Advantage

## Stratified Cox Proportional Hazard estimation

|                               | All                  | Northern Countries   | DCs                  | LDCs                | Asia                 |

Robust z statistics in parentheses

\* significant at 10%; \*\* significant at 5%; \*\*\* significant at 1%

---

# Conclusions

- Median export duration is 2 years for the whole sample (7'819'052 obs)
  - Initially large exports will have longer duration
  - Robust negative relationship between the distance to comparative advantage and the export survival.
  - Further robustness check using Parametric Survival (Duration) Models
-

---

Thank you very much

---
